

# Freigabe ins Internet

## Zertifikate

- Zertifikate kann man nur erhalten, wenn man einen DNS Namen hat, z.B. `wolke.qg-moessingen.de`. der Host muss auf Port 80 und Port 443 erreichbar sein.
- Problem: Die IP-Adresse an einem Hausanschluss ändert sich gelegentlich.
- Lösung: Ein „Dyndns“ Provider, z.B. `dynv6.com`

## DynDNS mit dynv6.com

- <https://dynv6.com/> öffnen und einen Host/Domainnamen wählen - gültige Mailadresse angeben.
- Bestätigungsmaile öffnen, Bestätigungslink anklicken
- Melde dich bei `dynv6.com` an
- Auf dem Nextcloud Server das Paket `ddclient` installieren: `apt install ddclient`. Alle Rückfragen kann man zunächst bei der Installation mit Enter leer lassen und bestätigen.
- Editiere die Datei `/etc/ddclient.conf`:

```
ssl=yes
protocol=dyndns2
use=web, web=ipify-ipv4
server=dynv6.com
login=None
password='DEIN_TOKEN_AUS_DEINEM_ACCOUNT'
DEINHOST.DEINE.DOMAIN
```

Anschließend kannst du die Funktion auf der Kommandozeile testen:

```
ddclient -daemon=0 -debug -verbose -noquiet -force
```

und

ddclient -daemon=0 -debug -verbose -noquiet

Wenn das klappt, kann man den ddclient-Daemon neu starten: `systemctl restart ddclient.service`, mit `journalctl -f -u ddclient` kann man die Meldungen des Daemons im Log anschauen.

## Portweiterleitung am Router

- Demo an den PT mit der Fritz Box der Schule.
- Port 80 und 443 sollten an die interne IP-Adresse der Cloud weitergeleitet werden.

## Zertifikat erhalten mit mod\_md

- Mod-MD Paket installieren: `apt install libapache2-mod-md`
- SSL und Mod-MD bei apache anschalten: `a2enmod ssl md` und `systemctl restart apache2` Nun muss man die Datei `/etc/apache2/sites-enabled/000-default.conf` anpassen, so dass sie wie unten aussieht - `meinecloud.dns.army` muss dabei allerdings durch einen DynDNS Namen ersetzt werden.

```
ServerName meinecloud.dns.army

MDomain meinecloud.dns.army
MDContactEmail certifica@ua25.de
MDCertificateAgreement accepted
MDPrivateKeys RSA 4096

<VirtualHost *:80>
    # The ServerName directive sets the request scheme, hostname and port
    # that
    # the server uses to identify itself. This is used when creating
    # redirection URLs. In the context of virtual hosts, the ServerName
    # specifies what hostname must appear in the request's Host: header to
    # match this virtual host. For the default virtual host (this file) this
    # value is not decisive as it is used as a last resort host regardless.
    # However, you must set it for any further virtual host explicitly.
